GOAL
To simulate ice and water circulation in Lake Erie over a yearly cycle, a Great Lakes Ice-circulation Model (GLIM) was developed by applying a Coupled Ice-Ocean Model (CIOM) with a 2-km resolution grid. The hourly surface wind stress and thermodynamic forcings for input into the GLIM are derived from meteorological measurements interpolated onto the 2-km model grids. The seasonal cycles for ice concentration, thickness, velocity, and other variables are well reproduced in the 2003/04 ice season. Satellite measurements of ice cover were used to validate GLIM with a mean bias deviation (MBD) of 7.4%. The seasonal cycle for lake surface temperature is well reproduced in comparison to the satellite measurements with a MBD of 1.5%. Additional sensitivity experiments further confirm the important impacts of ice cover on lake water temperature and water level variations. Furthermore, a period including an extreme cooling (due to a cold air outbreak) and an extreme warming event in February 2004 was examined to test GLIM’s response to rapidly-changing synoptic forcing.

The goal of GLIM development is to add ice forecasts to an existing nowcast/forecast system in the Great Lakes. In addition, GLIM will also be used to test hypotheses related to lake ice dynamics and climate change.

Science Behind Forecasts
The Great Lakes Coastal Forecasting System (GLCFS) presently predicts lake water circulation, temperature, and surface waves (http://www.glerl.noaa.gov/GLCFS). Since it currently does not have a lake-ice component, empirical methods have been used to keep the system running over the winter. Wave forecasts also must be modified, as ice cover dampens surface waves significantly during winter. Thus, it is inadequate to use only a circulation model to investigate hydrodynamics and thermodynamics when lake ice is present. The increasing need for predicting lake ice for navigation, weather forecasting, rescue efforts, and ecosystem studies motivated us to develop a coupled ice-circulation model.

Status
GLIM was developed and validated against satellite measurements for an ice season 2003-2004. GLIM was tested to be incorporated into the GLERL’s Great Lakes Coastal Forecasting System for the ice season 2009-2010. GLIM will be run for the period 1990 to present to investigate the interannual variability of lake ice and its response to the changing climate.
